APPLICATION FOR LETTERS PATENT

**Multiple User Authentication for Online Console-Based
Gaming**

Inventor(s):

Darren Anderson

Tony Chen

Boyd Multerer

ATTORNEY'S DOCKET NO. MS1-766US

1 **TECHNICAL FIELD**

2 This invention relates to console-based gaming systems, and more
3 particularly, to methods for authenticating multiple identities in a single
4 reply/request exchange between a game console and an authentication entity.
5

6 **BACKGROUND**

7 Traditionally, gaming systems with a dedicated console were standalone
8 machines that accommodated a limited number of players (e.g., 4). PC-based
9 gaming grew in popularity in part due to the ability to play games online with
10 many remote players over a network (e.g., the Internet). Thus, one trend for
11 dedicated gaming systems is to provide broadband capabilities to facilitate online
12 gaming. Microsoft Corporation recently announced its Xbox™ video gaming
13 system that is equipped with a hard disk drive to enhance gaming, and broadband
14 connectivity to support online gaming.

15 Creating an online gaming system for a dedicated console poses several
16 unique and difficult problems. One problem concerns authentication of the
17 participants. To establish an online gaming event, a local game being played on
18 one game console goes online and communicates with other game consoles,
19 players, and/or online services. This involves some level of trust among the
20 participants, which the game attempts to establish by identifying itself, the game
21 console, and the one or more players currently on the machine to other participants
22 on the network in a secure manner. Additionally, the game console may also want
23 to discover trusted services with which it can communicate over the network.

24 The PC-based games do not experience such problems. For instance, PC-
25 based games do not typically experience multiple simultaneous users; rather only a

1 single user is involved in the online game. On a PC, the users can easily enter
2 their data via keyboard and the trusted services are easily configurable. Also, PC
3 users tolerate network operations that take a little longer. If the PC game takes
4 five extra seconds to start because it is making multiple round-trips to an
5 authentication server, no one will complain. This is not the case in the gaming
6 world.

7 Accordingly, the constraints on a dedicated game console make
8 authentication a difficult problem for the following reasons:

- 9
- 10 • Consoles do not have keyboards. Game controllers are not efficient
- 11 data-entry devices, thus user-entered data should be kept to a minimum.
- 12 • Gaming systems are plug-and-go; they plug into the wall and are ready
- 13 for play. Configuration is not expected or tolerated in the game console
- 14 community.
- 15 • Console games should be playable with as little start up time as
- 16 possible. Players expect to put a game disk into the console, turn it on,
- 17 and be playing the game a few seconds later.
- 18 • Consoles are a closed development environment in order to ensure high
- 19 content quality. Thus, consoles need to know that they are
- 20 communicating with trusted, quality controlled services. The need for
- 21 trusted communications is further driven by the addition of a hard disk
- 22 drive into the console in that any malicious damage rendered to the hard
- 23 disk drive's data by an external source makes it difficult or impossible
- 24 to repair without reformatting.
- 25

1 Cheating is not yet a major problem in the online console-based gaming
2 community. In anticipation that it might one day pose a problem, there is a need
3 for a solution that addresses cheating. Part of the solution is to make the console
4 itself as secure as possible and tamper resistant, such that any tampering by a user
5 will be discovered or render the console inoperable. While security and tamper
6 resistant solutions help, it does not prevent the case where a rogue player writes
7 PC software to emulate a console machine on the network, enabling cheating
8 without a game console.

9 To prevent such impostor cheating, there is a need for an authentication
10 protocol that verifies a player claiming to be on a console machine really is that
11 player, as well as guarantees that the game console is indeed a trusted game
12 console and not an impostor or one that has been compromised.

13 14 **SUMMARY**

15 A console-based multi-user authentication process allows multiple users of
16 a game console to be authenticated together in a single request/reply exchange
17 with an authentication entity.

18 In the described implementation, the game console is equipped with a hard
19 disk drive, a portable media drive, and broadband connectivity to enable network
20 access to a ticket issuing entity and one or more online services. When the game
21 console desires to use the online service, it first obtains a ticket for that service
22 from the ticket issuing entity. The game console submits a request to the ticket
23 issuing entity that contains a game console identity, the identities of the multiple
24 users, and an identity of the desired online service.

1 In response, the ticket issuing entity generates a ticket containing the game
2 console identity and the multiple user identities together encrypted with the online
3 service's key. The ticket issuing entity returns the ticket to the game console,
4 which passes it onto the online service. The online service uses the ticket to verify
5 the authenticity of the game console and the multiple users. In this manner, the
6 single ticket obtained from the ticket issuing entity proves the particular game
7 console as well as the multiple user identities playing at the game console.

8 The game console identity is created when the game console first
9 establishes a game account for online gaming. During manufacturing, the game
10 console is constructed with pieces of information that may be made available
11 programmatically (e.g., hard disk ID, CPU ID, serial number, random number, a
12 value derived as a function of an ID or serial number, a quantity or some other
13 mark written onto the hard drive, etc.). This information is recorded in a database,
14 which is subsequently made available to an authentication server. When the game
15 console seeks a game account, it submits the pieces of information to the
16 authentication server. Using the database, the server evaluates whether the pieces
17 are legitimate and correspond to a game console that has not yet established an
18 account. If the evaluation proves positive, a game account is created for that game
19 console and the game console identity is assigned to the game console.

20 21 **BRIEF DESCRIPTION OF THE DRAWINGS**

22 Fig. 1 illustrates a gaming system with a game console and one or more
23 controllers.

24 Fig. 2 is a block diagram of the gaming system.
25

Fig. 3 illustrates a network gaming system in which the Fig. 1 gaming system is connected via a network to other consoles, services, and a ticket issuing entity.

Fig. 4 illustrates a multi-user authentication process involving three participants: a game console, a ticket issuing entity, and an online service.

Fig. 5 is a flow diagram of the multi-user authentication process that facilitates authentication of multiple identities—game console, game title, multiple users.

Fig. 6 is a flow diagram of a process for establishing a game console identity that is used in the multi-user authentication process.

DETAILED DESCRIPTION

The following discussion is directed to console-based online gaming systems and techniques for authenticating multiple identities—game console, game title, multiple users—in one authentication roundtrip. The discussion assumes that the reader is familiar with basic cryptography principles, such as encryption, decryption, authentication, hashing, and digital signatures. For a basic introduction to cryptography, the reader is directed to a text written by Bruce Schneier and entitled, “Applied Cryptography: Protocols, Algorithms, and Source Code in C,” published by John Wiley & Sons, copyright 1994 (second edition 1996), which is hereby incorporated by reference.

Gaming System

Fig. 1 shows an exemplary gaming system 100. It includes a game console 102 and up to four controllers, as represented by controllers 104(1) and 104(2).

1 The game console 102 is equipped with an internal hard disk drive and a portable
2 media drive 106 that supports various forms of portable storage media as
3 represented by optical storage disc 108. Examples of suitable portable storage
4 media include DVD, CD-ROM, game discs, game cartridges, and so forth.

5 The game console 102 has four slots 110 on its front face to support up to
6 four controllers, although the number and arrangement of slots may be modified.
7 A power button 112 and an eject button 114 are also positioned on the front face
8 of the game console 102. The power button 112 switches power to the game
9 console and the eject button 114 alternately opens and closes a tray of the portable
10 media drive 106 to allow insertion and extraction of the storage disc 108.

11 The game console 102 connects to a television or other display (not shown)
12 via A/V interfacing cables 120. A power cable 122 provides power to the game
13 console. The game console 102 may further be configured with broadband
14 capabilities, as represented by the cable or modem connector 124 to facilitate
15 access to a network, such as the Internet.

16 Each controller 104 is coupled to the game console 102 via a wire or
17 wireless interface. In the illustrated implementation, the controllers are USB
18 (Universal Serial Bus) compatible and are connected to the console 102 via serial
19 cables 130. The controller 102 may be equipped with any of a wide variety of
20 user interaction mechanisms. As illustrated in Fig. 1, each controller 104 is
21 equipped with two thumbsticks 132(1) and 132(2), a D-pad 134, buttons 136, and
22 two triggers 138. These mechanisms are merely representative, and other known
23 gaming mechanisms may be substituted for or added to those shown in Fig. 1.

24 A memory unit (MU) 140 may be inserted into the controller 104 to
25 provide additional and portable storage. Portable memory units enable users to

1 store game parameters and port them for play on other consoles. In the described
2 implementation, each controller is configured to accommodate two memory units
3 140, although more or less than two units may be employed in other
4 implementations.

5 The gaming system 100 is capable of playing, for example, games, music,
6 and videos. With the different storage offerings, titles can be played from the hard
7 disk drive or the portable medium 108 in drive 106, from an online source, or from
8 a memory unit 140. A sample of what the gaming system 100 is capable of
9 playing back include:

- 11 1. Game titles played from CD and DVD discs, from the hard disk drive,
12 or from an online source.
- 13 2. Digital music played from a CD in the portable media drive 106, from a
14 file on the hard disk drive (e.g., Windows Media Audio (WMA) format),
15 or from online streaming sources.
- 16 3. Digital audio/video played from a DVD disc in the portable media drive
17 106, from a file on the hard disk drive (e.g., Active Streaming Format),
18 or from online streaming sources.

19
20 Fig. 2 shows functional components of the gaming system 100 in more
21 detail. The game console 102 has a central processing unit (CPU) 200 and a
22 memory controller 202 that facilitates processor access to various types of
23 memory, including a flash ROM (Read Only Memory) 204, a RAM (Random
24 Access Memory) 206, a hard disk drive 208, and the portable media drive 106.
25 The CPU 200 is equipped with a level 1 cache 210 and a level 2 cache 212 to

temporarily store data and hence reduce the number of memory access cycles, thereby improving processing speed and throughput.

The CPU 200, memory controller 202, and various memory devices are interconnected via one or more buses, including serial and parallel buses, a memory bus, a peripheral bus, and a processor or local bus using any of a variety of bus architectures. By way of example, such architectures can include an Industry Standard Architecture (ISA) bus, a Micro Channel Architecture (MCA) bus, an Enhanced ISA (EISA) bus, a Video Electronics Standards Association (VESA) local bus, and a Peripheral Component Interconnects (PCI) bus also known as a Mezzanine bus.

As one suitable implementation, the CPU 200, memory controller 202, ROM 204, and RAM 206 are integrated onto a common module 214. In this implementation, ROM 204 is configured as a flash ROM that is connected to the memory controller 202 via a PCI (Peripheral Component Interconnect) bus and a ROM bus (neither of which are shown). RAM 206 is configured as multiple DDR SDRAM (Double Data Rate Synchronous Dynamic RAM) that are independently controlled by the memory controller 202 via separate buses (not shown). The hard disk drive 208 and portable media drive 106 are connected to the memory controller via the PCI bus and an ATA (AT Attachment) bus 216.

A 3D graphics processing unit 220 and a video encoder 222 form a video processing pipeline for high speed and high resolution graphics processing. Data is carried from the graphics processing unit 220 to the video encoder 222 via a digital video bus (not shown). An audio processing unit 224 and an audio codec (coder/decoder) 226 form a corresponding audio processing pipeline with high fidelity and stereo processing. Audio data is carried between the audio processing

unit 224 and the audio codec 226 via a communication link (not shown). The video and audio processing pipelines output data to an A/V (audio/video) port 228 for transmission to the television or other display. In the illustrated implementation, the video and audio processing components 220-228 are mounted on the module 214.

Also implemented on the module 214 are a USB host controller 230 and a network interface 232. The USB host controller 230 is coupled to the CPU 200 and the memory controller 202 via a bus (e.g., PCI bus) and serves as host for the peripheral controllers 104(1)-104(4). The network interface 232 provides access to a network (e.g., Internet, home network, etc.) and may be any of a wide variety of various wire or wireless interface components including an Ethernet card, a modem, a Bluetooth module, a cable modem, and the like.

The game console 102 has two dual controller support subassemblies 240(1) and 240(2), with each subassembly supporting two game controllers 104(1)-104(4). A front panel I/O subassembly 242 supports the functionality of the power button 112 and the eject button 114, as well as any LEDs (light emitting diodes) or other indicators exposed on the outer surface of the game console. The subassemblies 240(1), 240(2), and 242 are coupled to the module 214 via one or more cable assemblies 244.

Eight memory units 140(1)-140(8) are illustrated as being connectable to the four controllers 104(1)-104(4), i.e., two memory units for each controller. Each memory unit 140 offers additional storage on which games, game parameters, and other data may be stored. When inserted into a controller, the memory unit 140 can be accessed by the memory controller 202.

1 A system power supply module 250 provides power to the components of
2 the gaming system 100. A fan 252 cools the circuitry within the game console
3 102.

4 A console user interface (UI) application 260 is stored on the hard disk
5 drive 208. When the game console is powered on, various portions of the console
6 application 260 are loaded into RAM 206 and/or caches 210, 212 and executed on
7 the CPU 200. The console application 260 presents a graphical user interface that
8 provides a consistent user experience when navigating to different media types
9 available on the game console.

10 The game console 102 implements a cryptography engine to perform
11 common cryptographic functions, such as encryption, decryption, authentication,
12 digital signing, hashing, and the like. The cryptography engine may be
13 implemented as part of the CPU 200, or in software stored on the hard disk drive
14 208 that executes on the CPU, so that the CPU is configured to perform the
15 cryptographic functions.

16 The gaming system 100 may be operated as a standalone system by simply
17 connecting the system to a television or other display. In this standalone mode,
18 the gaming system 100 allows one or more players to play games, watch movies,
19 or listen to music. However, with the integration of broadband connectivity made
20 available through the network interface 232, the gaming system 100 may further
21 be operated as a participant in a larger network gaming community. This network
22 gaming environment is described next.

Network Gaming

Fig. 3 shows an exemplary network gaming environment 300 that interconnects multiple gaming systems 100(1), ..., 100(g) via a network 302. The network 302 represents any of a wide variety of data communications networks. It may include public portions (e.g., the Internet) as well as private portions (e.g., a residential Local Area Network (LAN)), as well as combinations of public and private portions. Network 302 may be implemented using any one or more of a wide variety of conventional communications media including both wired and wireless media. Any of a wide variety of communications protocols can be used to communicate data via network 302, including both public and proprietary protocols. Examples of such protocols include TCP/IP, IPX/SPX, NetBEUI, etc.

In addition to gaming systems 100, one or more online services 304(1), ..., 304(s) may be accessible via the network 302 to provide various services for the participants, such as hosting online games, serving downloadable music or video files, hosting gaming competitions, serving streaming audio/video files, and the like. The network gaming environment 300 may further involve a key distribution center 306 that plays a role in authenticating individual players and/or gaming systems 100 to one another as well as online services 304. The distribution center 306 distributes keys and service tickets to valid participants that may then be used to form games amongst multiple players or to purchase services from the online services 304.

The network gaming environment 300 introduces another memory source available to individual gaming systems 100—online storage. In addition to the portable storage medium 108, the hard disk drive 208, and the memory unit(s) 140, the gaming system 100(1) can also access data files available at remote

1 storage locations via the network 302, as exemplified by remote storage 308 at
2 online service 304(s).

3 4 **Multi-User Authentication**

5 To participate in an online gaming situation, it is desirable for every
6 participant to authenticate themselves to one another. Ideally, the entities that
7 should be authenticated include the users, the game title, the game console, and
8 any online service the might be involved. One approach to authenticating each
9 entity is to employ the well-known Kerberos authentication protocol, which is
10 described in the above referenced Schneier book. With the Kerberos
11 authentication protocol, each user would perform an independent authentication
12 cycle with the key distribution center because Kerberos is only used to
13 authenticate a single user identity at a time. Unfortunately, this results in multiple
14 authentication cycles for the various users, which is undesirable in the gaming
15 context.

16 To authenticate multiple users, the gaming system implements an
17 authentication process that allows simultaneous authentication of all entities—
18 game console, game title, and multiple users—in one request/reply exchange with
19 the key distribution center. Moreover, a single ticket can be used to prove the
20 particular game console and the multiple user identities playing at the game
21 console. This is very efficient and highly desirable in the gaming context. In the
22 described implementation, the process is a Kerberos-like authentication protocol.

23 Fig. 4 shows three primary participants in the multi-user authentication
24 process: the gaming system 100(1), an online service 304, and the key distribution
25 center 306. The participants are networked together via the network 302 (not

1 shown in Fig. 4) and are each capable of performing one or more routine
2 cryptographic functions, such as encryption, decryption, one way hashing, random
3 number generation, digital signing, and the like. Although more participants may
4 be involved in the online gaming event, the illustrated participants represent an
5 exemplary set of participants that are involved in the multi-user authentication
6 process.

7 For discussion purposes, suppose there are four users of the gaming system
8 100(1), as represented by the four controllers 104(1)-104(4). Each user is given an
9 identity U_1 , U_2 , U_3 , and U_4 and is assigned a user key K_1 , K_2 , K_3 , and K_4 . The
10 game console 102 is also assigned its own identity X and a game console key K_X .
11 (One exemplary approach to assigning the game console identity and key is
12 described below in more detail with reference to Fig. 6.) Additionally, the game
13 title, which is shown here as a game disc 108, is assigned a separate identity G . In
14 a similar manner, the online service 304 is assigned its own identity A and a key
15 K_A .

16 The multi-user authentication process may be understood as a four-step
17 process conducted in two roundtrip communication cycles. The first two steps
18 occur during a single roundtrip request/reply exchange between the gaming system
19 100(1) and the key distribution center 306, which is illustrated as paths 402 and
20 404. The latter two steps occur during a single roundtrip request/reply exchange
21 between the gaming system 100(1) and the online service 304, which is illustrated
22 as paths 406 and 408. Note that the 406 request and 408 response are usually
23 piggy backed on a regular online service request, and thus does not incur an extra
24 round trip. Thus, the full authentication process may be carried out very quickly,
25 with minimal information exchanges between the participants.

1 During the first request/reply exchange, the gaming system 100(1) submits
2 a request asking the key distribution center 306 to issue a single ticket on behalf of
3 all identities—game console X, game title G, and all four users U_1 , U_2 , U_3 , and U_4
4—for purposes of participating with the online service 304 (i.e., path 402 in Fig.
5 4). The key distribution center 306 generates and returns a ticket for use with the
6 desired online service (i.e., path 404 in Fig. 4). In this manner, the key
7 distribution center 306 functions as a ticket issuing entity that issues tickets for
8 services.

9 During the second request/reply exchange, the gaming system 100(1)
10 submits the ticket to the online service 304 for authentication (i.e., path 406 in Fig.
11 4). The ticket is piggyback information along with the first request for the online
12 service, and does not need to be sent in a separate request or until the service is
13 needed. If valid, the online service 304 sends back a reply that can be used by the
14 gaming system 100(1) to authenticate the online service 304 (i.e., path 408 in Fig.
15 4). If all entities are authenticated, the gaming system 100(1) can trust the
16 returned results from the online service and can continue to interact with the
17 online service 304.

18 The process illustrated in Fig. 4 is advantageous in that a single ticket
19 obtained from the key distribution center 306 is used to prove the game console
20 and the multiple user identities playing at the game console. This is much more
21 efficient than the traditional approach where multiple tickets are needed, one for
22 each authenticated principal.

23 Fig. 5 shows the multi-user authentication process 500 that is implemented
24 by the three participants of Fig. 4. The process can be implemented in software as
25 computer-executable instructions stored on various storage media at the

1 participants. When executed, the instructions direct the various participants to
2 perform operations illustrated as blocks in Fig. 5. The tasks are illustrated beneath
3 headings "Key Distribution Center", "Game Console", and "Online Service" to
4 convey an exemplary location as to which entities are performing them. The
5 multi-user authentication process 500 will be described with reference to both
6 Figs. 4 and 5.

7 At block 502 in Fig. 5, the game console 102 generates validated user
8 identities based on the user identities U_1 , U_2 , U_3 , and U_4 and user keys K_1 , K_2 , K_3 ,
9 and K_4 . More specifically, the validated user identities include the user identities
10 and values derived from the user keys. The validated user identities will be
11 submitted with the request and used to demonstrate to the key distribution center
12 306 that the gaming system has knowledge of the user key and hence, implicitly
13 authenticates the users.

14 One way to generate the key derivative value is to compute a cryptographic
15 hash of the user key using the key of the game console. For user U_1 with key K_1 , a
16 hash H_1 is computed as follows:

$$17 \quad H_1 = \text{HMAC}_{K_x}(K_1)$$

18
19
20 The hash H_1 forms the key derivative value. Another way is to encrypt the
21 current time using the user key K_1 , as follows:

$$22 \quad H_1 = E_{K_1}(T)$$

1 Once again, the resulting value H_1 forms the key derivative value. The
2 validated user identity is the combination of the user identity U_1 and the
3 corresponding key derivative value H_1 :

$$\text{Validated User Identity} = (U_1, H_1).$$

7 At block 504 in Fig. 5, the game console 102 constructs a request
8 containing the game console identity X , the game title identity G , the online
9 service identity A of the service being requested, and multiple validated user
10 identities (U_1, H_1) , (U_2, H_2) , (U_3, H_3) , and (U_4, H_4) . The request has the following
11 identity string:

$$\text{Request} = [X, G, A, (U_1, H_1), (U_2, H_2), (U_3, H_3), (U_4, H_4)]$$

15 If the gaming system wanted authentication for more than online service,
16 the identities of other services B , C , ..., etc. are added to the request.
17 Additionally, the request may include a version of the authentication protocol and
18 a random nonce generated by the game console to resist replay attacks. The
19 request may further include a checksum value to be used to verify receipt of the
20 entire identity string. The game console 102 submits the request over the network
21 302 to the key distribution center 306 (i.e., path 402).

22 At block 506 in Fig. 5, the key distribution center 306 evaluates the request
23 as well as the identities contained in the request. The distribution center 306
24 generates a random session key to be used for each service being requested by the
25 gaming system 100(1). In this example, the center 306 generates a random session

1 key K_{XA} to be used during the second communication cycle involving the game
2 console 102 and the online service 304. If other services are requested, additional
3 random session keys K_{XB} , K_{XC} , ..., etc. are produced.

4 At block 508 in Fig. 5, the key distribution center 306 generates a ticket
5 that will subsequently be presented to the requested online service. There is one
6 ticket issued for each service requested, but each ticket is effective for multiple
7 users. The ticket contains the identity string submitted in the request. It also
8 includes a time T_G that the ticket is generated, a time T_L identifying the time length
9 before expiration of the ticket, and the randomly generated session key K_{XA} for the
10 service requested. The ticket contents are encrypted via a symmetric key cipher
11 (e.g., DES) that utilizes the online service's key K_A , as follows:

$$\text{TicketA} = E_{K_A}[T_G, T_L, K_{XA}, X, G, A, U_1, U_2, U_3, U_4]$$

15 Notice that the ticket does not carry the corresponding key derivative values
16 H_i . Once the authentication server reads the key derivative values and believes the
17 game console knows the user keys, the authentication server places the identities
18 of the users within the issued tickets. Individual online services will subsequently
19 believe in whatever the ticket tells it and hence do not need to see the key
20 derivative values H_i .

21 If the gaming system sought tickets for more than one service, the key
22 distribution center 306 issues multiple tickets, each ticket being encrypted with the
23 public key of the desired online service, as follows:

$$\text{TicketB} = E_{K_B}[T_G, T_L, K_{XB}, X, G, B, U_1, U_2, U_3, U_4]$$

$$\text{TicketC} = E_{K_C}[T_G, T_L, K_{X_C}, X, G, C, U_1, U_2, U_3, U_4]$$

:

$$\text{TicketN} = E_{K_N}[T_G, T_L, K_{X_N}, X, G, N, U_1, U_2, U_3, U_4]$$

At block 510 in Fig. 5, the key distribution center 306 returns each ticket over the network 302 to the gaming system 100(1) (i.e., path 404). Since the game console 102 does not know the online service's key K_A , the game console 102 cannot open the ticket and alter the contents. The key distribution center also returns the session keys in an attached encrypted message. The session key message contains the ticket generation time T_G , the ticket expiration length T_L , and one or more session keys K_{X_A} , K_{X_B} , K_{X_C} , etc., and all contents are encrypted using the game console's key K_X , as follows:

$$\text{Session Key Message} = E_{K_X}[T_G, T_L, K_{X_A}, K_{X_B}, K_{X_C}, \dots]$$

Since the session key message is encrypted with the game console's key K_X , the game console 102 is able to open the session key message and recover the session time parameters and session keys.

At block 512 in Fig. 5, the game console 102 passes the ticket, as is, onto the online service 304 (i.e., path 406). The game console 102 also generates and sends the current time T (instead of its own ID) encrypted with the random session key K_{X_A} , as follows:

$$\text{Time Message} = E_{K_{X_A}}[T]$$

1 At block 514 in Fig. 5, the online service 304 evaluates the authenticity of
2 the ticket. It decrypts the ticket using its key K_A to recover the contents, as
3 follows:

$$4 \quad D_{K_A}[\text{TicketA}] = T_G, T_L, K_{XA}, X, G, A, U_1, U_2, U_3, U_4$$

6
7 The decrypted contents include the session key K_{XA} . The online service
8 then uses the session key K_{XA} to decrypt the time message and recover the time T ,
9 as follows:

$$10 \quad D_{K_{XA}}[\text{Time Message}] = T$$

11
12
13 The online service 304 compares the recovered time sent from the game
14 console with the current time. If the recovered time is not within an allowable
15 time horizon from the current time, the online service deems the game console 102
16 as not authentic and the ticket as a forgery. In this case (i.e., the “No” branch from
17 block 516), the online service denies service to the game console.

18 On the other hand, if the recovered time is within an allowable time
19 window from the current time, the online service is assured that the game console
20 102 is authentic. In this case (i.e., the “Yes” branch from block 516), the online
21 service generates a reply containing the time T in the request Time Message,
22 encrypted with the session key K_{XA} , as follows:

$$23 \quad \text{Reply} = E_{K_{XA}}[T]$$

1 At block 518, the online service 304 returns the reply over the network 302
2 to the gaming system 100(1) (i.e., path 408). Once again, this reply is
3 piggybacked on a regular online service reply and does not incur an extra
4 communication trip.

5 At block 520 in Fig. 5, the game console 102 evaluates the authenticity of
6 the reply. The game console 102 decrypts the reply using the session key K_{XA} that
7 it previously received in the session key message from the key distribution center
8 306. If the game console 102 can successfully decrypt the reply, and the T value is
9 the same as the T value originally sent in the Time Message, the game console is
10 assured that the online service is authentic because the online service could not
11 otherwise have known the random session key K_{XA} . In this case (i.e., the "Yes"
12 branch from block 522), the game console is free to interact with the services
13 offered by the online service (block 524). Otherwise, if the reply cannot be
14 decrypted successfully (i.e., the "No" branch from block 522), the game console
15 deems the online service as not authentic and forgoes its services.

16 The multi-user authentication process is built atop the three-participant
17 model in the Kerberos authentication process. It differs from Kerberos in that it
18 allows authentication of multiple users simultaneously, with one trip to the key
19 distribution center and one ticket for all users. The extension involved, in part,
20 defining new message strings to be passed among the participants.

21 An alternative implementation is to leverage the existing well-defined data
22 packets employed in the conventional Kerberos protocol. Kerberos defines a
23 packet that includes a data field known as the "Pre-Auth" data field for pre-
24 authorized data. In the alternate implementation, the multiple validated user
25 identities (U_1, H_1) , (U_2, H_2) , (U_3, H_3) , and (U_4, H_4) are inserted into this "Pre-

1 Auth" data field so that all users are authenticated in the same request. Also the
2 Kerberos tickets issued would be modified to contain extra "Authorization Data"
3 that contains the user identities that have been authenticated (U_1, U_2, U_3, U_4).
4

5 Establishing Game Console Identity and Key

6 The above multi-user authentication protocol hinges in part on the ability to
7 establish the game console identity X and associated game console key K_X . This
8 section describes how these parameters are created in the first place.

9 Generally, each game console 102 is manufactured with secret information
10 that is very difficult to guess and very difficult to access. Tamper resistant designs
11 are employed to physically protect the secret information on the game console
12 from attacks on the hardware. The secret information is stored at a backend server
13 for use later at account creation time to verify whether the game console is
14 authentic. The secret information may be the same for all or a batch of consoles,
15 or unique for each console. Preferably, the secret information is unique so that if
16 the information is compromised, only a single fake account can be created.

17 The establishment of a secure game console identity relies on the fact that
18 console manufacturing is a regulated process and that all consoles have consistent
19 characteristics, regardless of the manufacturing date. It also relies on the fact that
20 because manufacturing is controlled by one or a limited number of entities, a
21 robust and secure database of the secret information unique to each machine can
22 be generated and used on the backend to verify that a particular game console is,
23 in fact, a real console at the time a game console account is being created.

24 Fig. 6 illustrates a process 600 for constructing a game console with secret
25 information for use in establishing a console identity X and game console key K_X .

1 The process 600 is performed in part during manufacturing and in part during
2 account creation in which an online gaming account for the game console is
3 created. These two phases are distinguished in Fig. 6 by a horizontal dashed line.
4 The tasks are illustrated beneath headings "Manufacturing", "Authentication
5 Server" and "Game Console" to convey exemplary locations as to where the tasks
6 are performed.

7 At block 602, the manufacturer constructs the game console to incorporate
8 one or more pieces of information at the time of manufacture. The information is
9 preferably of the type that can be made available programmatically. In one
10 implementation, the game console is built to include at least two pieces of
11 information, one that is unique to the individual machine and a second that is very
12 difficult to guess and access. The first piece of information need not be evenly
13 distributed across a name space, nor does it need to be secret or hard to read, but it
14 does need to be unique across the name space and accessible programmatically.
15 For example, the first piece of information could be a console serial number
16 assigned by the manufacturer, a hard disk ID printed on the hard disk drive, or a
17 serial number of any chip, ROM, firmware, or the like. This first piece of
18 information will be used as the "name" of the game console to look up which row
19 in table 650 corresponds to the particular game console.

20 The second piece of information does not necessarily need to be unique per
21 machine, but is evenly distributed across its namespace. It is very difficult to
22 guess and very difficult to access. Programmatic access is permitted via secure
23 techniques, such as code-signing techniques, but physical access is controlled via
24 hardware-based solutions that resist tampering and render physical attack and
25 reverse engineering very difficult. Examples of the second piece of information

1 include a CPU ID or a value derived from the CPU ID, such as a one-way hash of
2 the CPU ID. Another example is a random key written onto disk at manufacturing
3 time, the disk drive needs to be protected from unauthorized reading (like using
4 the CPU ID) through some other means. This second piece of information will be
5 used as the "key" for the game console, to prove that the game console is genuine
6 and not some other computing device pretending to be a game console.

7 At block 604, the information is recorded in a database at the manufacturer
8 as a set of database records 650. Each record includes, for example, an identity of
9 the console, the hard disk ID (HDID), and the CPU ID. At block 606, the database
10 records 650 are securely made available to an authentication server that may or
11 may not be hosted by the key distribution center 306. In one implementation, a
12 secure database replication procedure is employed to securely transfer the console
13 information database to the authentication server. It is further noted that the same
14 entity may or may not control the manufacturing and authentication server.

15 At this point, the two pieces of information can be used in the verification
16 of the game console and creation of the game console identity X and key K_X .
17 Such information can be used to verify, for example, that the game console is valid
18 and not an impersonating personal computer.

19 This completes the manufacturing phase of process 600. The game
20 consoles are subsequently released from manufacturing and sold to consumers.
21 When the user first decides to play an online game or access online services, the
22 game console first obtains an account. This initiates the account creation phase of
23 the process 600 in Fig. 6.

24 At block 610, the game console submits the information, or data derived
25 from the information, to the authentication server. The information could be sent

1 over a secure link (e.g., SSL) established between the game console and the
2 authentication server. In one implementation, the game console submits the hard
3 disk ID and the CPU ID assuming a secure connection is established, such as
4 using SSL to protect the contents of the message. To avoid exposing the CPU ID,
5 another implementation is to submit in place of the CPU ID, a one-way hash
6 digest of the CPU ID in such a way that it is extremely difficult to deduce the CPU
7 ID from the resulting value. Another way to prove knowledge of the CPU ID and
8 to also prevent replay attacks is to send $E_{\text{CPUID}}(T)$ where the current time is
9 encrypted with the CPU ID as the Key.

10 At block 612, the authentication server evaluates the information from the
11 game console. In one implementation, the authentication server uses the
12 information as an index into the console database records 650 to identify that the
13 information is a correct combination of pieces. For instance, the authentication
14 server determines whether the hard disk ID and CPU ID passed in from the game
15 console form a correct pair recorded in the database as belonging to the same
16 game console. If there is a match, the authentication server can be assured that the
17 client is a valid game console because it would be very difficult for an impostor to
18 guess, manually or programmatically, both pieces of information and their
19 relationship.

20 At block 614, the authentication server looks up in the console database
21 records to determine whether an account has already been established for this
22 information. If no account exists (i.e., the "No" branch from block 614), the
23 authentication server creates an account and assigns a unique game console
24 identity X and a randomly generated key K_X to that account (block 616). If an
25 account exists (i.e., the "Yes" branch from block 614), the authentication server

1 retrieves the existing account information (block 618). The game console identity
2 X and key K_X are returned to the game console (block 620).

3 At block 622, the game console stores the game console identity X and key
4 K_X in a secure way to resist hardware attacks. It also sends back a message
5 containing the identity X and the identity encrypted with the key K_X , or $E_{K_X}(X)$.
6 Having the game console return a message allows the authentication server to
7 ascertain whether the game console correctly received the account data. If the
8 decrypted identity matches the non-encrypted identity, the game console received
9 the account data correctly. If the two do not match, the game console received
10 incorrect data and the authentication server should delete the account and restart
11 the process at block 610. If no reply is received from the game console, the
12 authentication server cannot be sure if the account data successfully made it to the
13 game console. In this case, the authentication server flags the account and waits
14 for another new account creation for this game console (signifying that the game
15 console did not receive the account data) or a successful logon (indicating that the
16 game console did receive the account data).

17 At game time, the actual security of the console machine is achieved via the
18 identity X and key K_X , as described previously in the multi-user authentication
19 process.

21 Conclusion

22 The above processes are advantageous for many reasons. First, the multi-
23 user authentication process is fast because it accomplishes all authentication for
24 the gaming system, including multiple users, the game title, and the machine itself,
25 in a single roundtrip communication with the key distribution center. After this

1 initial roundtrip, the game console is able to communicate with any trusted
2 services without re-communicating with the key distribution center. The whole
3 process is accomplished with minimal user input and minimal delay before play
4 can begin. The single ticket obtained from the authentication server is also unique
5 in that it not only proves the particular game console, but also the multiple user
6 identities playing at the game console. This is in contrast to the traditional
7 approach where multiple tickets would need to be used (one for each authenticated
8 principal).

9 Although the invention has been described in language specific to structural
10 features and/or methodological acts, it is to be understood that the invention
11 defined in the appended claims is not necessarily limited to the specific features or
12 acts described. Rather, the specific features and acts are disclosed as exemplary
13 forms of implementing the claimed invention.
